50 meter salinity field

ABSTRACT

The physical oceanography of the shelf and slope waters of the New York Bight (Block Island to Cape May) in August of 1974 is described. Temperature, salinity, and density data, presented in surface contours and section profiles, showed the shelf/slope front, a cold core on the shelf, and a salinity core on the slope. Geostrophic currents in the slope water were inferred from the density structure, and showed two anticyclonic eddies with maximum geostrophic velocities of approximately 40 cm s^{-1}. Temperature and salinity profiles indicated shelf/slope mixing related to the eddies.

INTRODUCTION

An oceanographic survey of the waters of the New York Bight (Block Island to Cape May) was conducted by the USCGC EVERGREEN during August 1974. The purpose of the cruise was to continue data collection for use in a coastal surface current model to be used in Search and Rescue planning. The survey, conducted during the period 8–20 August, consisted of six sections laid perpendicular to the trend of the coast between Block Island, Rhode Island and Cape May, New Jersey (fig. 1). Each section was designed to contain two stations in the slope water beyond the continental shelf, one station on the continental slope, and four to five stations on the continental shelf, thus providing information on not only shelf processes, but also on the adjacent slope water. Station spacing was approximately 15 nautical miles, and section spacing was approximately 45 nautical miles. In addition to the oceanographic survey, three current meter arrays were deployed south of Long Island (fig. 1).

PROCEDURES

Oceanographic Sampling

At each station an STD (Salinity-Temperature-Depth) cast was taken to near bottom or to a depth of 1100 meters. The data was collected on a Plessey Environmental Systems Model 9040 S/T/D Environmental Profiling System (STD) (serial number 5313). The data were recorded on an analog trace and also digitally on magnetic tape. The digital recording was made by a Sonycraft Digital Data Logger (DDL) manufactured under Coast Guard contract CG–12, 778–A. Four channels of information were sampled at rates of 0.5 or 1.0 scans per second. STD frequencies representing depth, temperature, and salinity were converted to binary coded decimal (BCD) and recorded on a 7 channel IBM compatible magnetic tape at a bit density of 200 bpi. The resolution of the DDL system is ±one hertz. One hertz corresponds to .00344°/$_{oo}$, .018°C, and 1.90 meters in salinity, temperature, and depth respectively. The fourth information channel was available for recording sound velocity on the DDL, but it was not used. The tape format for each STD cast consisted of 3 sets of station data such as station number, position, date, and time followed by any number of data records, depending on the maximum depth and lowering rate of the cast. Each record consisted of the temperature and salinity information at 100 depth levels. Thus, an average one thousand meter cast was composed of about 1200 data levels recorded on approximately 12 records. Five computer programs were developed by CG OCEANOU to reduce the number of data levels to a more manageable figure of 50 to 100 data levels at standard depths and inflection points which would still accurately represent the original water column.

The computer programs were developed for a Control Data Corporation (CDC) 3300 computer. A flow diagram of the processing procedure described below is shown in figure 2. The first program, NEWDL, input the on deck depth frequency of the depth sensor, and read the records to be processed from the magnetic tape. The digitized frequencies were translated from BCD to engineering units of depth (meters to tenths), temperature (C° to hundredths), and salinity (°/$_{oo}$ to hundredths). The values were printed out so that an initial check of the data could be made. In addition, a tape output (NEWDL tape) was written as an input to the next program. With a rapid sample rate such as 0.5 second, a specific depth level might show up several times. While these temperature and salinity values were always close, they generally did not agree exactly, probably as a result of sensor lag. The output from the first program was normally around 1200 levels of data for a 1000 meter cast.

Program AVCOR averaged data levels inputed from the NEWDL tape at the same depth level. AVCOR accepted sequential levels until a deeper level was reached; then it began the averaging for the next level. Therefore if, due to the ship rolling, the STD dips to a lower level and then returns to the original level, the data at the original level subsequent to the roll will not be included in the average. During the AVCOR processing, corrections are made to temperature and salinity as discussed in the following section. The output of AVCOR is a printout and a magnetic tape (AVCOR tape). The printout of temperature, salinity, and computed sigma-t was quality controlled by removing samples which caused averaged sigma-t values to decrease more than 0.2, 0.05, or 0.02 per averaged data level within 0–100 meters, 100–300 meters, and deeper than 300 meters respectively.

Use of these criteria occasionally permitted data to pass which indicated large instabilities in the water column, as revealed by computation of the stability or E value (Sverdrup, et al. 1942, pp. 416–418). This usually occurred only over small intervals. (Although such data might be questioned, the data has not been rejected; this will permit other investigators to draw their own conclusions as to whether or not to use the data.

All data has been used in the analysis presented in this report.)

Program FINAV, which input the AVCOR tape, reaveraged the data after data levels which failed to pass the AVCOR sigma-t test were removed. The output of FINAV is a printout and a computer card deck. The FINAV printout was quality controlled by rechecking the sigma-t values to ascertain the effect of the data level deletions on the FINAV run. For various reasons, the zero meter depth level is not recorded by the DDL. Zero level data is obtained from the STD trace or extrapolation, and entered into the computer card deck.

The fourth program, SIGPT, determined the standard and significant levels, whose temperature and salinity would accurately represent the original water column. Standard levels were taken at the depths falling closest to minimum recorded depth, 10, 20, 30, 50, 75, and 100 meters, every 25 meters to 300 meters, and then every 50 meters to 1000 meters. The first test for significant levels consisted of fitting a cubic curve through five consecutive temperature data points. If the curvature at the midpoint exceeded an absolute value of 0.005, the second, third, and fourth points were compared with the data points immediately above and below. A level was significant if it departed from a straight line between the adjacent points by more than 0.04°C for temperature (more than 0.06°/$_{oo}$ for salinity). The second test compared the differences between the curvature of two successive midpoints. If the absolute value of the difference exceeded 0.005, the departure of the point from the adjacent points was again checked, using the same limits as in the first test to determine if the point was significant. If both of these tests were negative, the departure of levels from points immediately above and below was again checked. If the absolute departure was greater than 0.09 for both temperature and salinity, the level was significant. If the limits were not exceeded in any of the three tests, the level was not significant. After running the same checks for salinity, the top level of the five level group was dropped and the next new level was added onto the bottom end, and the testing was begun again. The output of SIGPT was a printout and computer card deck. The printout was checked for obvious errors such as wrong input.

The final program, SARCS, plots temperature, salinity, and sigma-t versus depth, and also plots a T-S diagram. The output, in addition to the plots, consists of a printout and computer card deck. The printout was subjected to a final quality control based on a careful study of the plots which indicated that the data reported herein was not grossly unreasonable. The card deck was submitted to NODC. (*Note*: Recent changes to standardize the data processing procedures at the CG Oceanographic Unit have resulted in some program name changes as well as minor changes in the way in which future data will be processed.)

Quality Control

STD data were quality controlled by comparing STD analog trace and DDL values with temperature and salinity values obtained from Niskin bottles attached just above the underwater sensor unit. Quality control (QC) samples were taken at the surface, 200, 500, and 1000 meters where possible. The Niskin bottle was equipped with protected (and for the 500 and 1000 meter samples, unprotected) deep sea reversing thermometers. The thermometers were allowed to soak for six minutes at each QC depth to reach equilibrium before the Niskin bottle was tripped. The conductivity ratios of the quality control samples were determined using an inductive laboratory salinometer and were converted to salinities utilizing the method established in the International Oceanographic Tables published jointly by UNESCO and the National Institute of Oceanography of Great Britain (1966).

The difference between STD and quality control values of temperature, salinity, and depth were plotted against the station numbers in the order in which they were occupied. Inspection of the plots indicated that the depth and temperature values should be corrected by values which did not change throughout the cruise. The correction for salinity values appeared to go through three phases, becoming worse as the cruise progressed. The final corrections shown in Table 1 were based on the average corrections for surface and 1000 meters. The correction for intermediate values was linearly interpolated. The data for 200 and 500 meters indicated that

TABLE 1.—STD Environmental Profiling System Data Corrections

Parameter	*Level*	*Correction*	*Remarks*
Depth	0 m	0 m	All Stations
Depth	1000 m	−16 m	All Stations
Temperature	0 m	−0.01°	All Stations
Temperature	1000 m	+0.01°	All Stations
Salinity	0 m	+0.01°/$_{oo}$	Stations 1–6, 53
Salinity	1000 m	−0.03°/$_{oo}$	Stations 1–6, 53
Salinity	0 m	+0.10°/$_{oo}$	Stations 7–17, 49–52, 54–68
Salinity	1000 m	+0.06°/$_{oo}$	Stations 7–17, 49–52, 54–68
Salinity	0 m	+0.16°/$_{oo}$	Stations 18–48
Salinity	1000 m	+0.15°/$_{oo}$	Stations 18–48

the actual correction should not have been linear; however, the 200 and 500 meter data did not seem sufficient to justify a more complex correction.

Navigation

Navigation during the cruise was based primarily on information from Loran-C. Loran-A, fathometer, satellite navigation (NAVSAT), and OMEGA were used as backup systems. Positions on most of the cruise were probably accurate to 0.2–0.4 nmi.

Current Meters

Three current meter arrays were set for a period of about 2 weeks south of Long Island (fig. 1). Array #1 consisted of a current meter at approximately 20 meters; array #2 consisted of current meters at approximately 20 and 40 meters; and array #3 consisted of a current meter at approximately 20 meters. The data from these current meters are now being analyzed and the results of the analysis are to be reported in a future publication by the Oceanographic Unit.

DATA PRESENTATION

Data Listing

Temperature, salinity, and depth values at standard levels of 0, 10, 20, 30, 40, 50, 75, 100, 150, 200, 250, 300, 400, 500, 600, 700, 800, 900, 1000, 1100, 1200, 1300, 1400 and 1500 meters, along with time, position, meteorological, and sea surface data were submitted to the National Oceanographic Data Center (NODC), which later provided printed data listings. In addition to the data submitted, the printed listings also contain values for sigma-t, specific volume anomaly, dynamic height, and sound velocity computed at NODC. The printed data listing for this cruise is contained in Appendix A.

Surface Contours

Surface values of temperature and salinity were plotted along the cruise track, and surface contours were produced from these values (figs. 3 and 4). The sea surface temperature contours from the cruise may be compared to those collected 19–21 August 1974 during a Coast Guard Airborne Radiation Thermometer flight (fig. 5).

Mean Vertically Averaged Sigma-t, σ_t

Column averaged values for sigma-t on the shelf were computed using the finite difference relationship

$$\sigma_t = \frac{1}{D} \sum_{i=0}^{n} \sigma_n Z_n$$

where $\sigma_n = (\sigma_t + \sigma_B)/2$ is the mean value of sigma-t in layer of thickness Z_n, σ_t and σ_B are the sigma-t values at the top and bottom of the layer respectively, and D the depth of the deepest observation, not to exceed 200m. Contours of mean vertically averaged sigma-t (fig. 6a) seem to be linked to the general summer circulation pattern which appears to parallel the coast (Bumpus, 1969).

Dynamic Height Contours

The general surface circulation along the eastern continental slope can be inferred from dynamic height contours (fig. 6b). Flow is parallel to the isopleths with high values to the right looking downstream. The assumptions and theory of inferring currents from dynamic heights are discussed in Sverdrup et al. (1942, pp. 451–457). Dynamic heights were referenced to the 1000 decibar level. The reference level was chosen using the method of Defant (1941). Dynamic heights for stations where the water depth was less than 1000 meters were calculated in a manner similar to that described by Helland-Hansen (1934).

The general pattern shown by the dynamic topography chart is a 10 to 30 cm s^{-1} southwesterly flow on the shelf and two anticyclonic circulations in the slope water. The southerly of the two circulations is obviously an eddy. Infrared satellite imagery subsequent to the cruise leaves little doubt that the northerly circulation is also an eddy.

Vertical Section Contours

Vertical sections for temperature, salinity, and sigma-t to a depth of 1000 meters were drawn for Sections A-F which were approximately normal to the coastline (figs. 7-24). A more meaningful presentation of vertical section contours was produced by greatly exaggerating the vertical distance scale in comparison to the horizontal distance scale.

RESULTS

The annual cycles of temperature and salinity on the continental shelf between Cape Cod and Cape Hatteras have been described by Bigelow (1933), Bigelow and Sears (1935), Walford and Wicklund (1968), and others. The conditions found in August 1974 were in general agreement with most features found by previous investigators (Table 2).

TABLE 2.—Comparison of Oceanographic Features in the New York Bight in August 1974 With Those Reported by Other Investigators

Feature	*August 1974*	*Other Investigators*
Sea surface temperature	20° to 25°C	20° to 25°C (Walford and Wicklund, 1968)
Temperature difference between surface and bottom at 35–50 meter contour zone	9° to 15°C	13 to 16°C (Bigelow, 1933) 15°C (Walford and Wicklund)
Sea surface salinity	<31°/$_{oo}$ to >35°/$_{oo}$	<32°/$_{oo}$ to >35°/$_{oo}$ (Bigelow and Sears, 1935)
Presence of cold core on shelf	Yes	Yes (Bigelow, 1933; Bigelow and Sears, 1935; Whitcomb, 1970)
Presence of high salinity core on slope	Yes	Yes (Bigelow and Sears, 1935; Whitcomb, 1970)
Presence of shelf/slope temperature front	Yes	Yes (Bigelow, 1933; Bigelow and Sears, 1935: Cresswell, 1967)
Presence of shelf/slope salinity front	Yes	Yes (Bigelow, 1933; Bigelow and Sears, 1935; Cresswell, 1967)

Cold Core

A cold core was found on the shelf at depths of 20 m. to 60 m. from the surface, at a distance of 20 to 70 nmi from the coast (fig. 7–12). This core, mentioned by Bigelow (1933), was defined by Whitcomb (1970), as having temperatures below 8°C. The pool or core is the remant of a winter shelf water formed at the surface (Whitcomb, 1970). Because of the southwesterly 0.2–0.5 nmi per day bottom drift along the shelf (Bumpus, 1965), there is some renewal of the core from the northeast, however, this renewal is probably minor compared to the annual renewal through surface cooling. The core, in August 1974, was found only at stations 11 and 21, thus it was considerably smaller than that shown in Whitcomb (1970) and than the 7.5°C core shown in Walford and Wicklund (1968). However, the presence of a cold core defined by the 10°C isotherm can be easily traced along the shelf from section F to section A (figs. 7–12). Evidence of a tongue related to the core was found at station 28. The source of this tongue can be traced northeast through station 37 to station 45 along the sigma-t surface of about 26.0. An alternative identification of a tongue as a "calved bubble" is discussed by Cresswell (1967).

High Salinity Core of Slope Water

Extending parallel to the shelf edge, and 5 to 10 nautical miles seaward from this edge, was a band of higher salinity water similar to that reported by Bigelow and Sears (1935) and others [Whitcomb (1970) for example]. This band is simply an expression of the impingement on the slope bottom of typical North Atlantic Central Water (Iselin, 1936), the surface of which has been freshed by mixing with shelf water. Following Whitcomb's (1970) example for September 1967 of defining the core as salinities greater than 35.75°/$_{oo}$, the defined core did not reach the surface, and its depth range was dependent on whether or not there was an eddy present.

On section A the core was characterized by an anticyclonic eddy which caused the cross-section of this core to increase considerably. Maximum salinity in the core section of this eddy was 36.2°/$_{oo}$, and the 35.75°/$_{oo}$ isohaline extended from about 20 to 375 meters. The defined core was absent on section B north of the eddy; on sections C and D it was found between about 70 to 120 meters. Sections E and F were influenced by a large eddy eastward of the sections, thus the defined core extended from about 30 to 210 meters and was still increasing in thickness at the end of the sections. The salinity and sigma-t profiles show little evidence for the 35.75°/$_{oo}$ core intersecting the bottom, although there is an obvious bottom salinity maximum over the shelf break.

Temperature/Salinity Correlations

The temperature salinity correlation for water present in the New York Bight during August 1974 could be accounted for in terms of the principal modes described by Hayes (1975) (figs. 25a, and 25b).

In August 1974 waters from the coastal area and contained within a band extending approximately 40 nautical miles offshore had characteristics that fell within an envelope with salinities less than 33.5°/$_{oo}$ (Envelope A, fig. 25a). Note that the lower portion of this envelope includes what Hayes called Middle Atlantic Bight Coastal Water. The lower portion of the envelope also represents the cold core previously described. The upper portion of the envelope reflects the warming effect of summer surface heating and the freshening effect of spring run-off.

Water from the centers of the two eddies fell within an envelope with salinities greater than 34.0°/$_{oo}$ (Envelope B, fig. 25a), displaying characteristics similar to those described as Regions 8 and 9 in "Physical Properties of the North Atlantic Ocean," Naval Oceanographic Office Publication #700, Section II (fig. 25b). This envelope could also be explained in terms of Hayes' Gulf Stream Water, Surface—and Mid-slope Water, and Deep Slope/North Atlantic Deep Water if allowance were made for summer warming of his Surface—and Mid-slope Water (fig. 25b).

At the stations between those found in the two envelopes the water shows the influence of mixing between the envelopes. Station 28 (fig. 25a) is an extreme example of this mixing. The water at the surface shows characteristics similar to that in envelope B; at depths of about 25 to 70 meters water derived from the cold core is encountered, below this the mid-slope water is found. An example of this type of mixing in shallower shelf water can be seen at station 12 (fig. 25a). Here the influence of surface water in envelope A is much stronger than that in envelope B. Another example of this type of mixing, in deeper slope water, can be observed at station 53 (fig. 25a). Here the influence of surface water from envelope A cannot be seen at all, and the influence of the cold low salinity core at the bottom of envelope A is slight. Similar situations are found for stations 6, 51, 50, 54, 55, and 49 around the southern eddy, and for station 26 near the northern eddy. These stations appear to basically represent slope or eddy water with which some shelf water has been mixed.

Station 29 on the shelf represents intrusion of slope and eddy derived water onto the shelf. This is apparent in the salinities of 35.5°/$_{oo}$ found around 30 meters.

Circulation

In coastal waters, where there is adequate fresh water discharge, a slope of the sea surface downward from the coast offshore is usually attributed to the increases in the steric anomaly related to run-off. The resulting dynamic gradient is associated with a steady flow turned to the right (in the northern hemisphere) and thus nearly parallel to the coast. Steady wind drift currents may modify this rough picture (Bum-

pus, 1969). In a recent Coast Guard Oceanographic Unit Technical Report, Bishop (1975) develops an operationally oriented technique to estimate these steady coastal currents. Input parameters to the model are the surface wind stress and mean vertically-averaged sigma-t gradient.

On the August 1974 cruise, measurements of sigma-t indicated a strong (i.e., 3×10^{-10}gm cm^{-4}) cross-shelf gradient in the vertically averaged sigma-t field. This is generally the typical summer density structure as contrasted to the weakly stratified (i.e., 1×10^{-10}gm cm^{-4}) winter shelf water. The summer wind field exhibits mean stress values of the order of 10^{-2} dynes/cm^{-2} toward the northeast while winter mean stress is in the 1 dyne/cm^{2} range toward the southwest according to data the for 5° square centered at 37.5°N 72.5°W as presented in Hidaka (1958). Both in summer and winter a south to southwest mean drift is derived from drift card data (Bumpus, 1969). It seems straightforward that this velocity field (approximately equal in magnitude for each season) is maintained in the summer months by the well developed density field, and in the winter by the mean wind stress.

Note added in proof. Recent computations of the mean winter wind stress in shelf waters shows the stress to be toward the northeast rather than the southwest. A paper by Beardsley and Butman (1974) suggest that along shore pressure gradient may be a significant factor in maintaining a mean southwest drift against the opposing mean wind stress.

Measured values of this mean vertically averaged sigma-t gradient, obtained on this cruise, were used in calculations to estimate surface coastal drift based on the above mentioned analytical model (wind stress was neglected). The result indicated a shelf circulation (fig. 6a) generally setting toward the southwest with maximum surface velocities near the shelf break of approximately of 20 cm/sec. This calculation approximates estimates of surface drift on the Mid-Atlantic shelf (Bumpus and Lauzier, 1965).

Comparison of the shelf circulation derived from this model (fig. 6a) with that derived from dynamic topography (fig. 6b) shows that the two are in general agreement but differ in details. The differences are probably related equally to differences in the governing equations (Bishop includes friction in his model) and to differences in applying the data (Bishop uses a mean sigma-t gradient for each section; the dynamic method uses the dynamic height for individual stations).

In waters seaward of the slope, contours of dynamic heights referenced to 1000 meters (fig. 6b) indicate the presence of two anticyclonic eddies with a trough between them. The slope circulation is dominated by the two eddies, the only other feature present being the trough. Maximum geostrophic speeds in the southern eddy are approximately 40 cm sec^{-1}.

An Anticyclonic Eddy in the Slope Water

One of the interesting features found during this cruise was the anticyclonic eddy located about 115 nmi southwest of Cape May, New Jersey (fig. 6b). Eddies such as this are a common feature in the slope water along the continental slope of the New York Bight. Infrared satellite imagery shows that there is a continual progression of such anticyclonic eddies through the Bight. They commonly have a diameter of 50 to 110 nmi with a spacing of about 110 to 220 nmi between eddies. The eddies seem to form from meanders in the North Atlantic Current in the northwest Atlantic, generally east of 65°W, and from there drift westward and southwestward along the continental slope until they reach the vicinity of Cape Hatteras where they rejoin the Gulf Stream (fig. 5).

The eddy southwest of Cape May appears on the temperature, salinity, and density sections as a core of warm saline water which is less dense than the surrounding water (figs. 7, 13, and 19). This core has a temperature of 15° to 16°C, a salinity of 36.1 to 36.2°/$_{oo}$, and a σ_t of 26.80 to 27.00.

Evidence of a second eddy located about 120 nmi south of Block Island was found on sections E and F (fig. 6). The center of the northern eddy was seaward of the available observations, and no conclusions can be drawn comparing the two eddies.

The circulation pattern around both eddies was anticyclonic, as indicated on the dynamic topography chart. The dynamic topography chart showed geostrophic speeds in the southern eddy of up to about 40 cm sec^{-1}.

Following the survey of the smaller eddy, a surface current drogue (fig. 26) was deployed

in the southwest quadrant of the eddy and tracked by LORAN C for 12 hours (fig. 27). The drogue was then recovered and re-deployed in the eddy's northern quadrant and tracked for about 36 hours (fig. 28). The tracks of the drogue can be accounted for satisfactorily by assuming that prior to and during the drogue experiment the eddy drifted southward at a speed of about 0.13 knots, and that the current acting on the drogue was the vector sum of the geostrophic flow in the eddy and a simple wind driven current as described in the National Search and Rescue Manual (1973). The estimated average winds for the tracking episodes are shown in Table 3. The effect of inertial currents can be seen in both of the drogue tracks. During the end of the eddy survey a storm was in progress with winds from the northeast quadrant of the compass at 20 to 25 knots. At about 1600Z on 11 August the wind dropped to 15 knots. This would have permitted an inertial current to begin rotating. The inertial period at the latitude of the eddy is 19.5 hours. It appears from figure 27 that the majority of the 12 hour drift of the southwest quadrant drogue track occurred predominantly during the portions of the inertial period in which there was a northward component to the inertial current. This would account for the northward displacement of the drogue after 12 hours relative to the position indicated by the combination of wind and geostrophic current. The second drogue track (fig. 28) indicates that when the drogue was launched the inertial current was flowing with a northwestward component. The westward movement of the drogue about one inertial period later (1600Z on 13 August) supports this drogue from the direct track between 2146Z on 12 August and 1600Z on 13 August represents the diameter of the inertial circle, one can calculate that the inertial velocity was 46 cm sec^{-1} (Neumann and Pierson, 1966; p. 158). A similar calculation on the drift from 1600Z on 13 August to 1115Z on 14 August when the drogue was recovered indicates that the inertial current had decreased to 38 cm sec^{-1}. These speeds agree with inertial speeds given by Pollard and Millard (1970).

It is of interest to speculate on the effect of eddies such as this in exchanging water between the slope and shelf areas. The average T-S characteristics above 30 meters of stations on the southwest side of the eddy are warmer and more saline than those on the northeast (fig. 29). This leads to the hypothesis that the anticyclonic eddies are a contributing factor in the mixing of shelf and slope waters. Another illustration of possible eddy-related mixing in process can be seen in the salinity profile of section A (fig. 13). The tongue of high salinity water found between 10 and 30 meters on stations 4 and 5 suggests that an eddy can cause intrusion of slope water onto the shelf.

APPENDIX A

OCEANOGRAPHIC DATA

Cruises Listed

Observed and interpolated oceanographic data taken by USCGC EVERGREEN, 8–20 August 1974 on SAR Cruise 3–74, prepared from NODC Listing No. 318408.

A complete description of the codes utilized in the tabulation of oceanographic station data can be found in National Oceanographic Data Center publication M–2, Processing Physical and Chemical Data from Oceanographic Stations. (Rev. August 1964, supplement issued May 1966.)

To facilitate use of the oceanographic station data listing, entry headings which are not self-explanatory are described below.

Depth to Bottom ---------- Corrected or uncorrected sounding in meters.
Max. Depth of Samples ------ Depth of deepest sample to nearest multiple of one hundred meters.

Wave observations

DIR. ---------- Rounded to nearest multiple of 10 degrees.
HGT. ---------- In increments of ½ m. Sum of 5 meters plus increments of ½ m if 50 is added to direction.
PER. ---------- If numerals 2 through 9 are entered, period in seconds is twice the numeric entry of 2X (numeric entry) +1. For other entries see WMO Code 3155.
SEA ---------- Sea state according to WMO Code 3700.

Weather Code ---------- If preceded by X, weather according to WMO Code 4501. If a two-digit entry, weather according to WMO Code 4677.

Cloud Code

Type ---------- Cloud type according to WMO Code 0500.
Amount ---------- Cloud amount in eights. Entry of the numeral 9 indicates cloud amount could not be estimated. (WMO Code 2700)

Water

Color Code ---------- Color according to Forel-Ule scale.
Trans. ---------- Transparency in whole meters as determined by Secchi disc.

Wind

Dir. ---------- Rounded to nearest multiple of 10 degrees.
Speed or Force ---------- If preceded by letter S, wind speed in knots; if preceded by letter F, wind force according to Beaufort scale.

Barometer ---------- Barometric pressure given in 10, units and tenths of millibars.

Air Temp. °C ---------- Air temperature to tenths of a degree centigrade.

Vis. Code ---------- Visibility according to WMO Code 4300.

No. obs. depths ---------- Number of observed levels associated with the station.

Messenger time ---------- Entered in hours and tenths of an hour GMT. For Nansen casts, indicates time of release of messenger applicable to the observational level. For STD casts, indicates the starting time of lowering the sensor.

Card type ---------- OBS designates observed levels. STD indicates the values at this standard level were interpolated by a modified 3-point LaGrange formula.

Depth (m) ---------- Depth to nearest meter. A postscript T indicates depth was obtained thermometrically; Z indicates uncorrected "wire out" depth. Postscript Q indicates value was marked doubtful by originator; P indicates value was considered doubtful by NODC. Postscripts P and Q retain this meaning throughout the following entries.

T°C ---------- Temperature to hundredths of a degree Centigrade.

S °/₀₀ ---------- Salinity in parts-per-thousand.

SIGMA-T ---------- Entered to hundredths.

Specific-volume ---------- Multiply entry by 10^{-7} to obtain specific-volume anomaly in cubic centimeters per gram.

ΣΔD Dyn. M. x 10^3 ---------- Multiply entry by 10^{-3} to obtain anomaly of dynamic height in dynamic meters referenced to the sea surface.

Sound Velocity ---------- Sound velocity according to Wilson's formula entered to tenths of a meter per second.

O_2 ml/l ---------- Dissolved oxygen in milliliters per liter entered to hundredths.

PO_4–P ug-at/l ---------- Inorganic phosphate in microgram-atoms per liter entered to hundredths.

Total-P ug-at/l ---------- Total phosphorus in microgram-atoms per liter entered to hundredths.

NO_2–N ug-at/l ---------- Nitrite-nitrogen in microgram-atoms per liter entered to hundredths.

NO_3–N ug-at/l ---------- Nitrite-nitrogen in microgram-atoms per liter entered to tenths.

SiO_4–Si ug-at/l ---------- Silicate-silicon in microgram-atoms per liter entered to whole units.

CHL-A ---------- Chlorophyll-A (total pigment) in milligrams per cubic meter entered to hundredths.
